Communication complexity

Classical communication complexity

[Yao, 1979]

E.g. equality function: $f(x, y) = 1$ if $x = y$, and 0 if $x \neq y$

Question: can the communication be less than n bits?

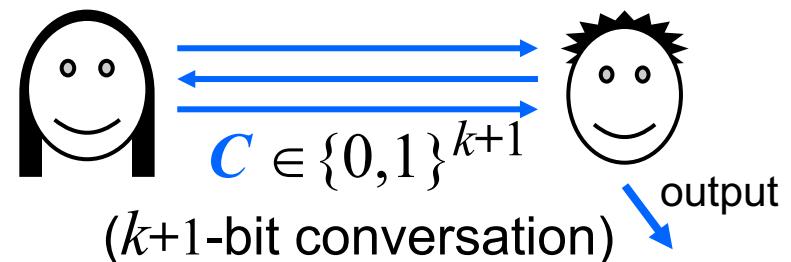

Deterministic cost is n bits (I)

Table of all values of $f(x,y)$:

000	001	010	011	100	101	110	111
000	1	0	0	0	0	0	0
001	0	1	0	0	0	0	0
010	0	0	1	0	0	0	0
011	0	0	0	1	0	0	0
100	0	0	0	0	1	0	0
101	0	0	0	0	0	1	0
110	0	0	0	0	0	0	1
111	0	0	0	0	0	0	1

Suppose the communication complexity of f is k

Each input in the domain of f fixes a **conversation** (including output)

Several inputs may lead to the same conversation ...

Definition: A (combinatorial) **rectangle** is $R \subseteq \{0,1\}^n \times \{0,1\}^n$ of the form $R = R_A \times R_B$

Deterministic cost is n bits (II)

Table of all values of $f(x,y)$:

	000	001	010	011	100	101	110	111
000	1	0	0	0	0	0	0	0
001	0	1	0	0	0	0	0	0
010	0	0	1	0	0	0	0	0
011	0	0	0	1	0	0	0	0
100	0	0	0	0	1	0	0	0
101	0	0	0	0	0	1	0	0
110	0	0	0	0	0	0	1	0
111	0	0	0	0	0	0	0	1

In fact, the inputs leading to C **must** constitute a rectangle: if $(x,y), (x',y')$ both lead to C then so do (x',y) and (x,y')

Since each conversation has a unique output, f is **constant** on each of these rectangles

Need at least 2^{n+1} rectangles to $\{0,1\}$ -partition this table

Since this implies $\geq 2^{n+1}$ distinct conversations, $k \geq n$

Therefore, the deterministic communication complexity is n

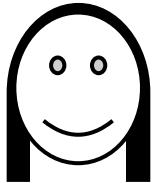

Probabilistic cost is $O(\log n)$ bits

Start with a “good” classical error-correcting code, which is a function
 $e: \{0,1\}^n \rightarrow \{0,1\}^{cn}$ such that, for all $x \neq y$,

$$\Delta(e(x), e(y)) \geq \delta cn \quad (\Delta \text{ means Hamming distance}),$$

where c, δ are constants

$x_1 x_2 \dots x_n$

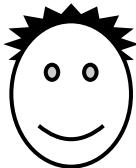

randomly choose

$$r \in \{1, 2, \dots, cn\}$$

$$(r, e(x)_r)$$

$y_1 y_2 \dots y_n$

output $\begin{cases} 1 & \text{if } e(y)_r = e(x)_r \\ 0 & \text{if } e(y)_r \neq e(x)_r \end{cases}$

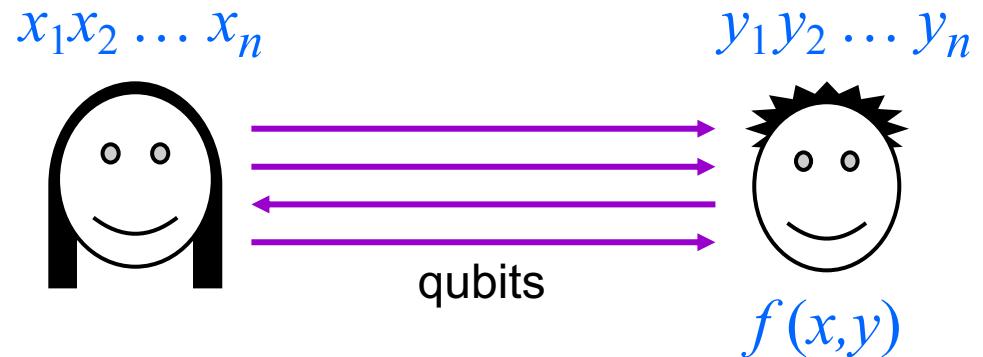

$$\begin{aligned} e(x) &= 1 0 1 1 1 0 \boxed{0} 1 0 1 1 0 0 1 1 0 0 1 \\ e(y) &= 0 1 1 0 1 0 \boxed{1} 1 0 0 1 1 0 0 1 0 1 0 \end{aligned}$$

Can repeat to reduce error

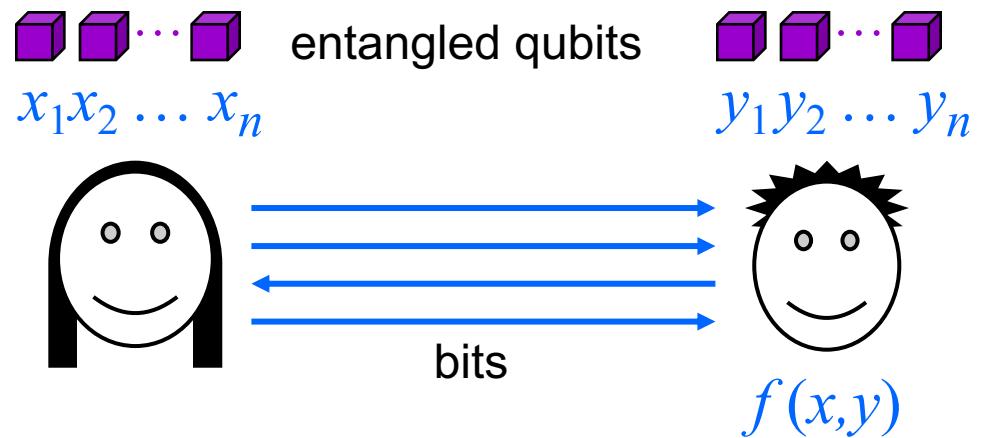

random k

Quantum communication complexity

Qubit communication

Prior entanglement

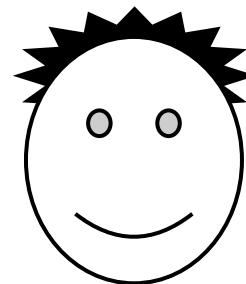

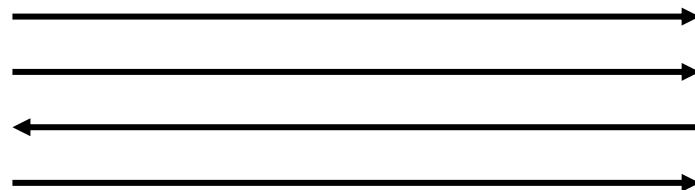

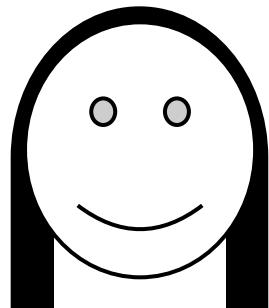

Question: can quantum beat classical in either of these contexts?

Appointment scheduling

(also known as the *Disjointness Problem*)

$$x = \begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & \dots & n \\ \boxed{0 & 1 & 1 & 0 & 1 & \dots & 0} \end{array}$$

$$y = \begin{array}{ccccccc} 1 & 2 & 3 & 4 & 5 & \dots & n \\ \boxed{1 & 0 & 0 & 1 & 1 & \dots & 1} \end{array}$$

$$i \quad (x_i = y_i = 1)$$

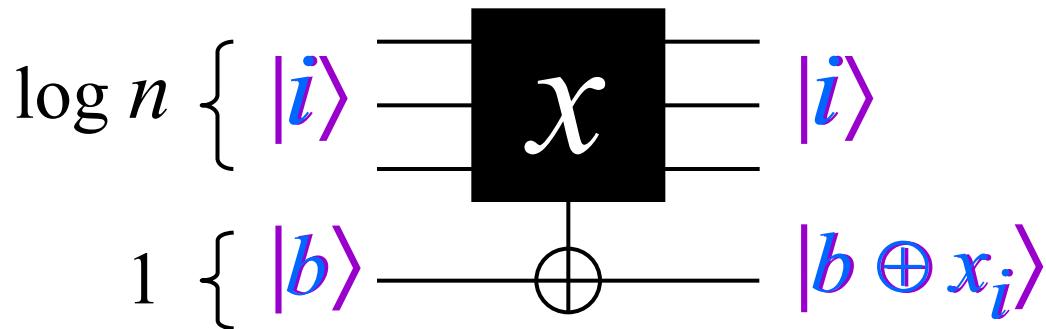

Classically, $\Omega(n)$ **bits** necessary to succeed with prob. $\geq 3/4$

For all $\varepsilon > 0$, $O(n^{1/2} \log n)$ **qubits** sufficient for error prob. $< \varepsilon$

[KS ‘87] [BCW ‘98]

Search problem

Given: $x = \boxed{0\ 0\ 0\ 0\ 1\ 0\ \dots\ 1}$ accessible via *queries*

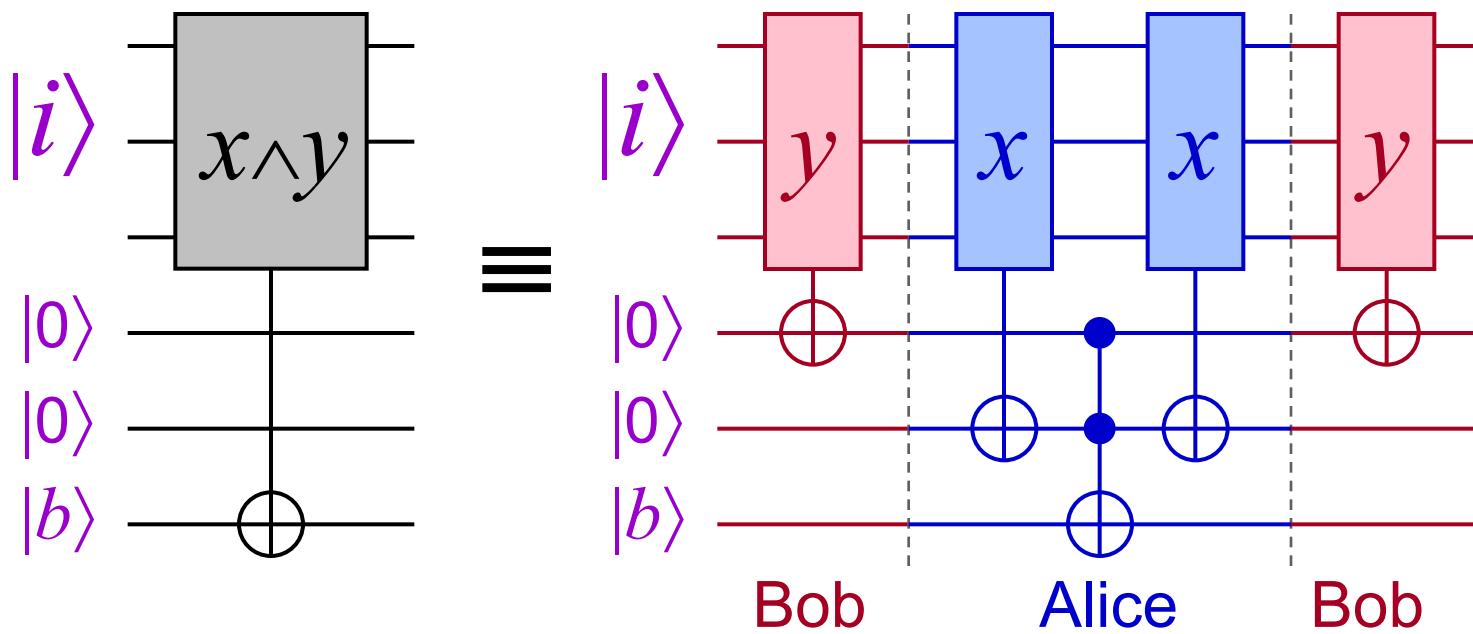

Goal: find $i \in \{1, 2, \dots, n\}$ such that $x_i = 1$

Classically: $\Omega(n)$ queries are necessary

Quantum mechanically: $O(n^{1/2})$ queries are sufficient

	1	2	3	4	5	6	...	n	
Alice									$x = \boxed{0 \ 1 \ 1 \ 0 \ 1 \ 0 \dots \ 0}$
Bob									$y = \boxed{1 \ 0 \ 0 \ 1 \ 1 \ 0 \dots \ 1}$
									$x \wedge y = \boxed{0 \ 0 \ 0 \ 0 \ 1 \ 0 \dots \ 0}$ (bitwise AND of x and y)

Communication per $x \wedge y$ -query: $2(\log n + 3) = O(\log n)$

Appointment scheduling: epilogue

Bit communication:

Cost: $\theta(n)$

Qubit communication:

Cost: $\theta(n^{1/2})$ (with refinements)

Bit communication
& prior entanglement:

Cost: $\theta(n^{1/2})$

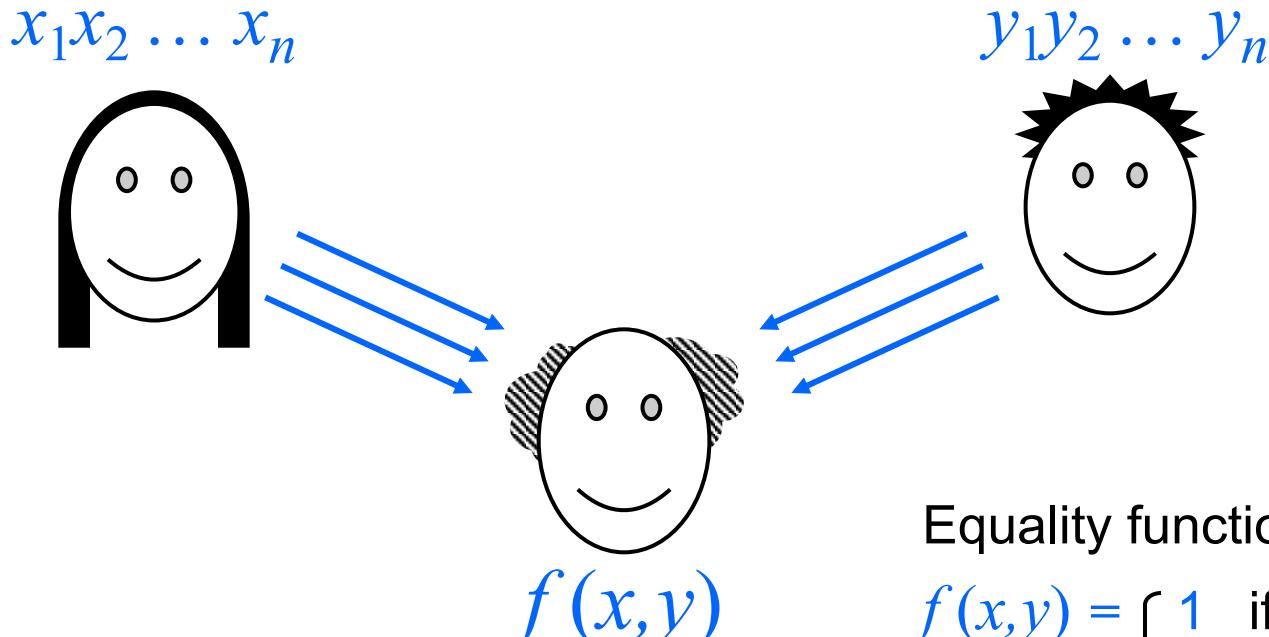

Qubit communication
& prior entanglement:

Cost: $\theta(n^{1/2})$

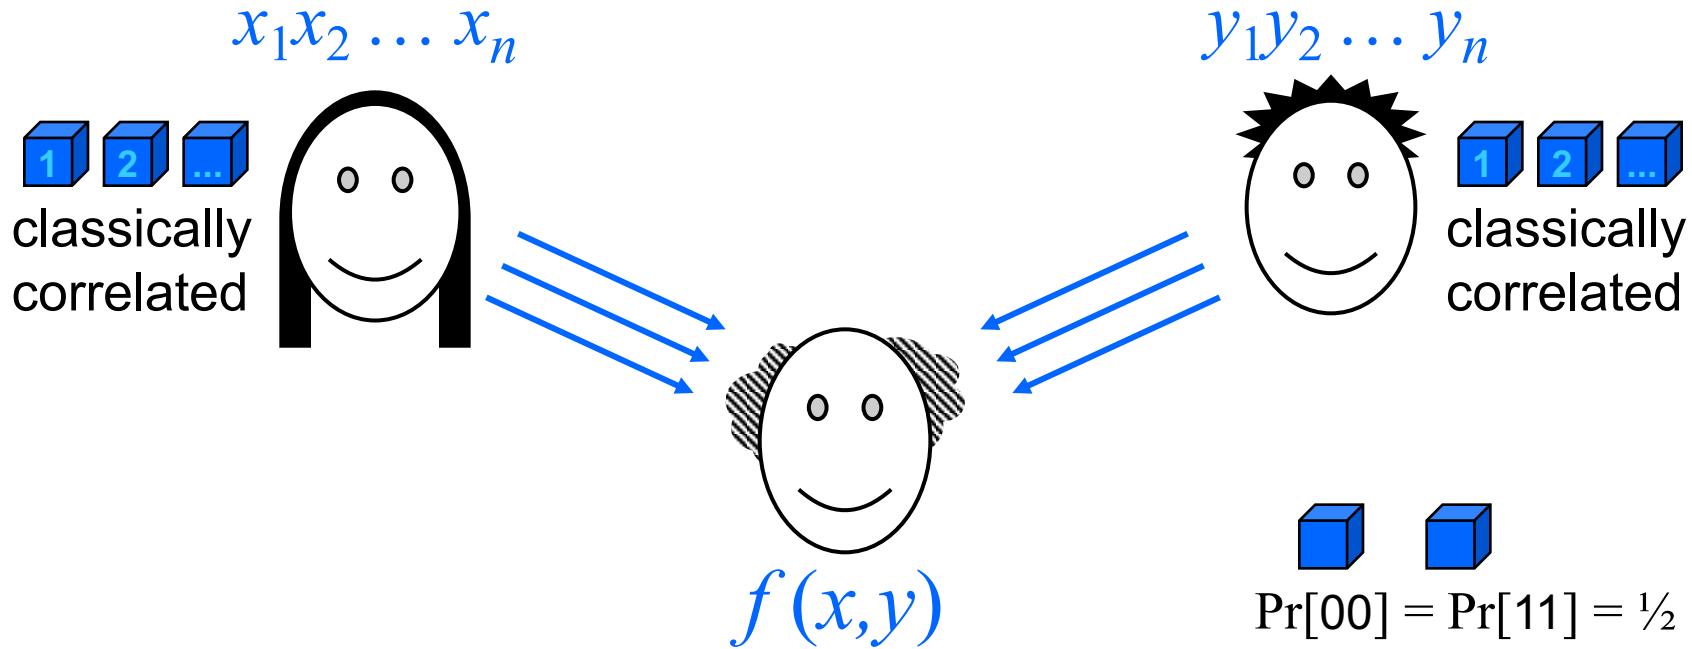

Quantum fingerprinting

Equality revisited in simultaneous message model

Exact protocols: require $2n$ bits communication

Equality revisited in simultaneous message model

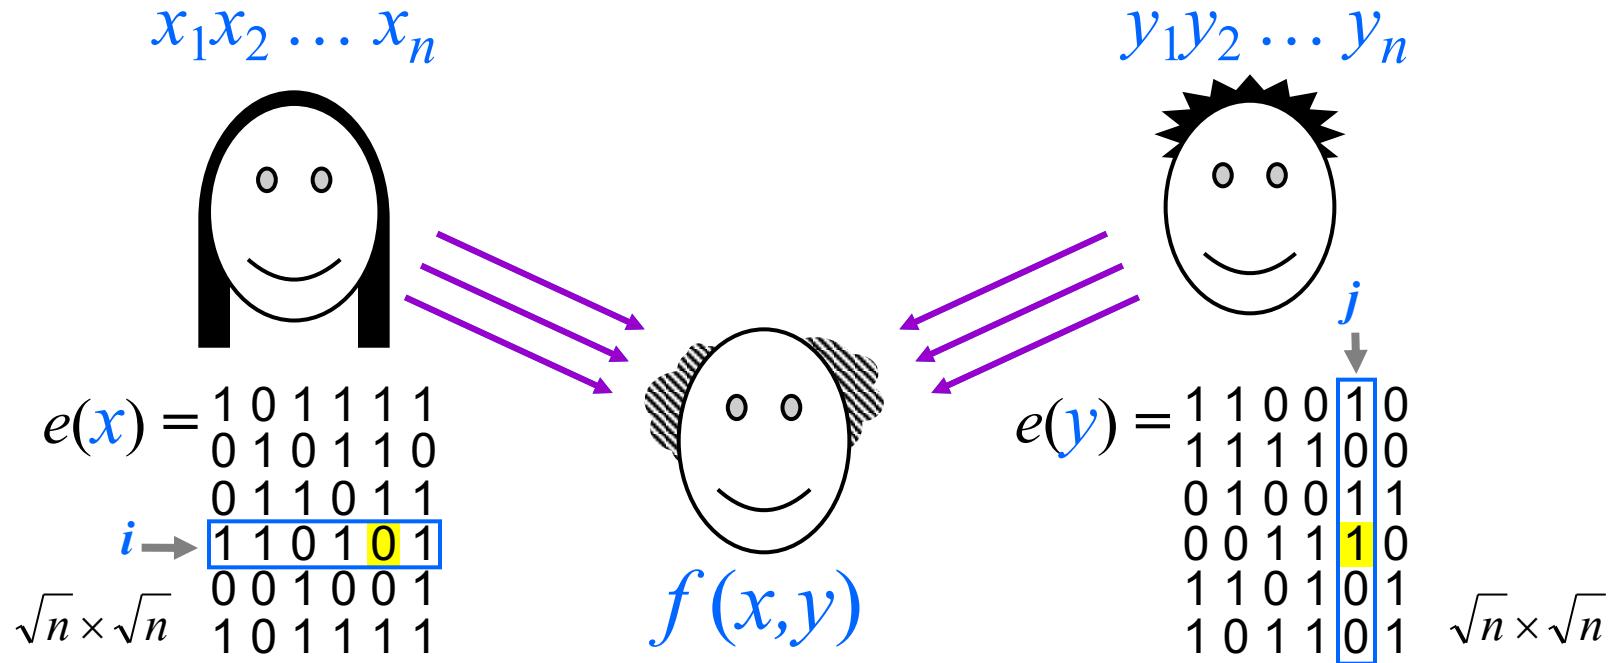

Bounded-error protocols with a shared random key: require only $O(1)$ bits communication

Error-correcting code: $e(\mathbf{x}) = 101111010110011001$
 $e(\mathbf{y}) = 011010010011001010$

random k

Equality revisited in simultaneous message model

Bounded-error protocols **without** a shared key:

Classical: $\theta(n^{1/2})$

Quantum: $\theta(\log n)$ using “quantum fingerprints”

Quantum fingerprints

Question 1: how many orthogonal states in m qubits?

Answer: 2^m

Let ε be an arbitrarily small positive constant

Question 2: how many ***almost orthogonal**** states in m qubits? (* where $|\langle \psi_x | \psi_y \rangle| \leq \varepsilon$)

Answer: $2^{2^{am}}$, for some constant $0 < a < 1$

Construction of *almost orthogonal states*: start with a special classical error-correcting code, which is a function $e: \{0,1\}^n \rightarrow \{0,1\}^{cn}$ such that, for all $x \neq y$,

$$\delta cn \leq \Delta(e(x), e(y)) \leq (1 - \delta)cn \quad (c, \delta \text{ are constants})$$

Construction of almost orthogonal states

Set $|\Psi_x\rangle = \frac{1}{\sqrt{cn}} \sum_{k=1}^{cn} (-1)^{e(x)_k} |k\rangle$ for each $x \in \{0,1\}^n$ ($\log(cn)$ qubits)

Then $\langle \Psi_x | \Psi_y \rangle = \frac{1}{cn} \sum_{k=1}^{cn} (-1)^{[e(x) \oplus e(y)]_k} |k\rangle = 1 - \frac{2\Delta(e(x), e(y))}{cn}$

Since $\delta cn \leq \Delta(e(x), e(y)) \leq (1-\delta)cn$, we have $|\langle \Psi_x | \Psi_y \rangle| \leq 1 - 2\delta$

By duplicating each state, $|\Psi_x\rangle \otimes |\Psi_x\rangle \otimes \dots \otimes |\Psi_x\rangle$, the pairwise inner products can be made arbitrarily small: $(1-2\delta)^r \leq \varepsilon$

Result: $m = r \log(cn)$ qubits storing $2^n = 2^{(1/c)2^{m/r}}$ different states

(as opposed to n qubits!)

What are these almost orthogonal states good for?

Question 3: can they be used to somehow store n bits using only $O(\log n)$ qubits?

Answer: No—recall that Holevo's theorem forbids this

Here's what we *can* do: given two states from an almost orthogonal set, we can distinguish between these two cases:

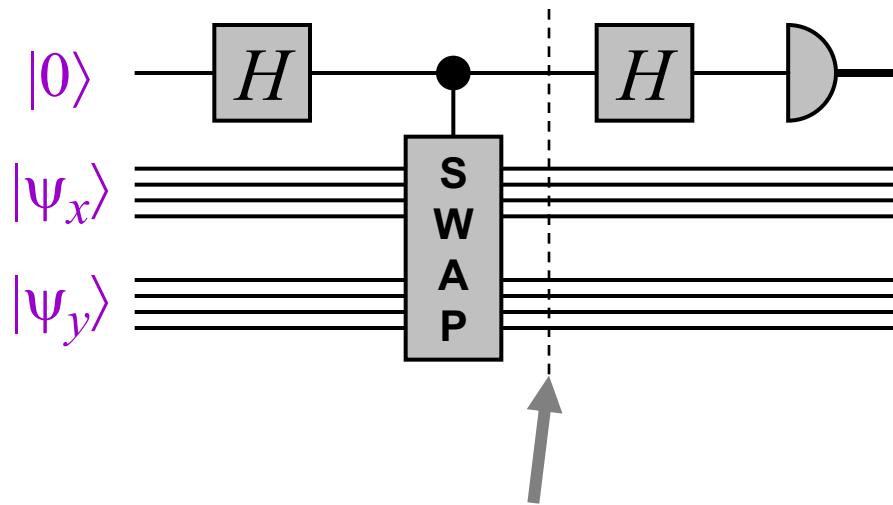

- they're both the same state
- they're almost orthogonal

Question 4: How?

Quantum fingerprints

Let $|\psi_{000}\rangle, |\psi_{001}\rangle, \dots, |\psi_{111}\rangle$ be 2^n states on $O(\log n)$ qubits such that
 $|\langle\psi_x|\psi_y\rangle| \leq \varepsilon$ for all $x \neq y$

Given $|\psi_x\rangle|\psi_y\rangle$, one can check if $x = y$ or $x \neq y$ as follows:

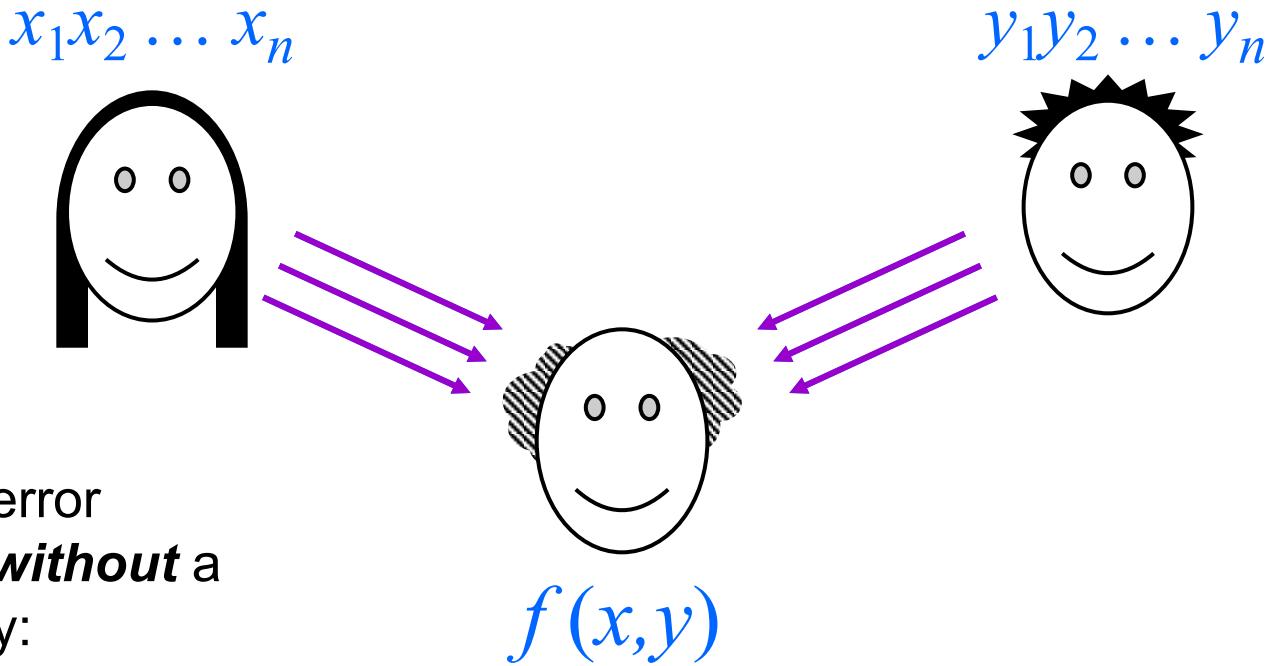

Intuition: $|0\rangle|\psi_x\rangle|\psi_y\rangle + |1\rangle|\psi_y\rangle|\psi_x\rangle$

if $x = y$, $\Pr[\text{output} = 0] = 1$
if $x \neq y$, $\Pr[\text{output} = 0] = (1 + \varepsilon^2)/2$

Note: error probability can
be reduced to $((1 + \varepsilon^2)/2)^r$

Equality revisited in simultaneous message model

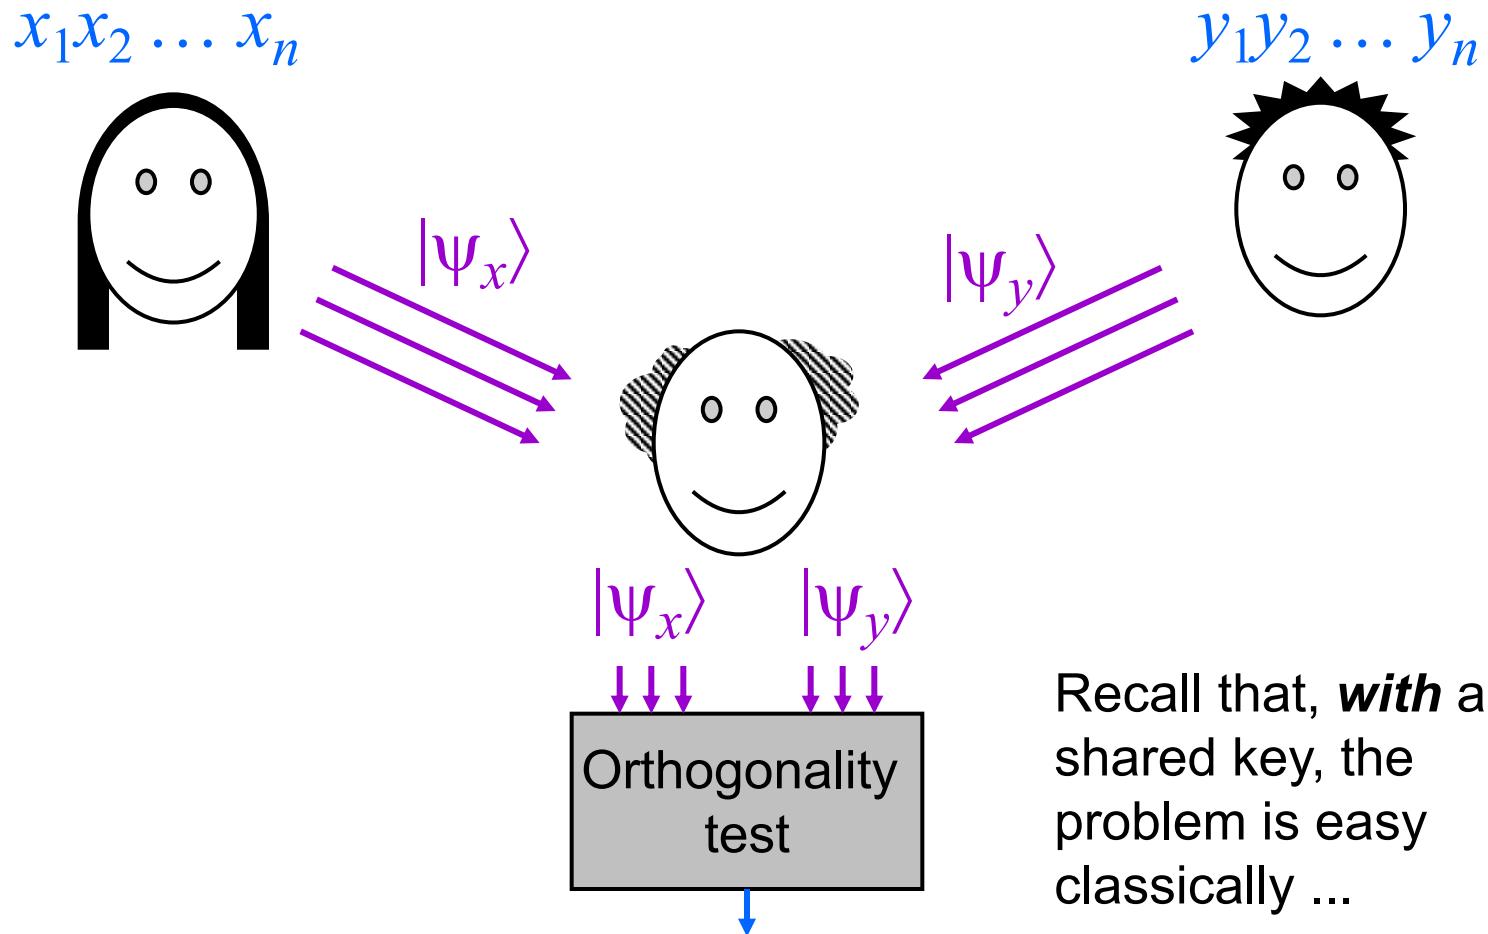

Bounded-error
protocols **without** a
shared key:

Classical: $\theta(n^{1/2})$

Quantum: $\theta(\log n)$

Quantum protocol for equality in simultaneous message model

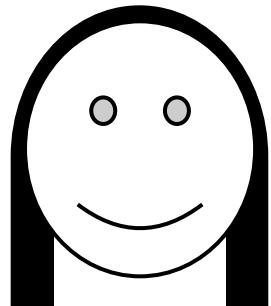

Recall that, **with** a shared key, the problem is easy classically ...

This quantum protocol only requires $\theta(\log n)$ qubits

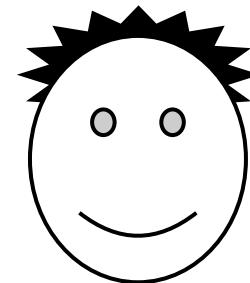

Inner product

Inner product function

$x_1 x_2 \dots x_n$

$y_1 y_2 \dots y_n$

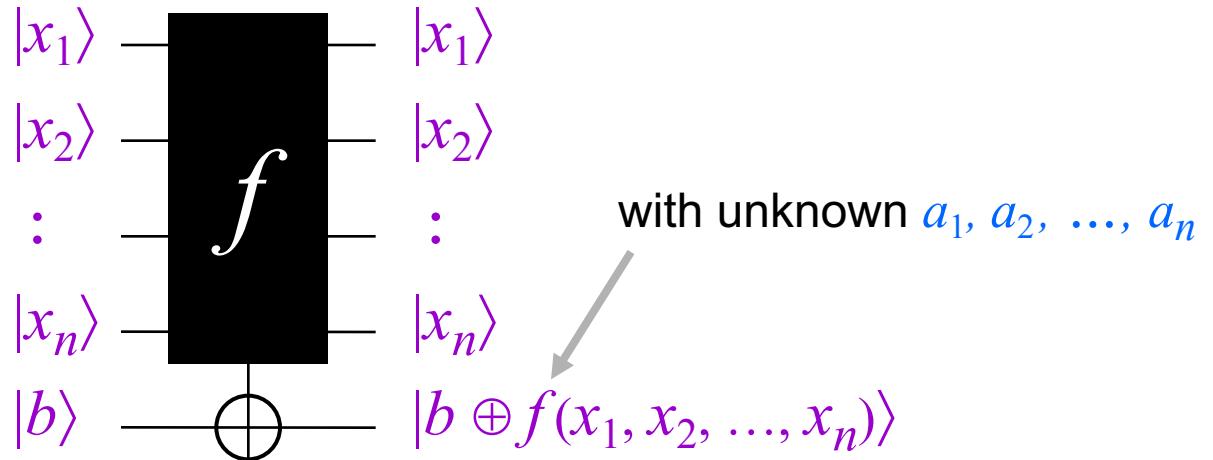

$f(x,y)$

$$f(x,y) = x \cdot y = x_1 y_1 + x_2 y_2 + \dots + x_n y_n \bmod 2$$

Aside: Bernstein-Vazirani problem I

Let $f(x_1, x_2, \dots, x_n) = a_1 x_1 + a_2 x_2 + \dots + a_n x_n \bmod 2$

Given:

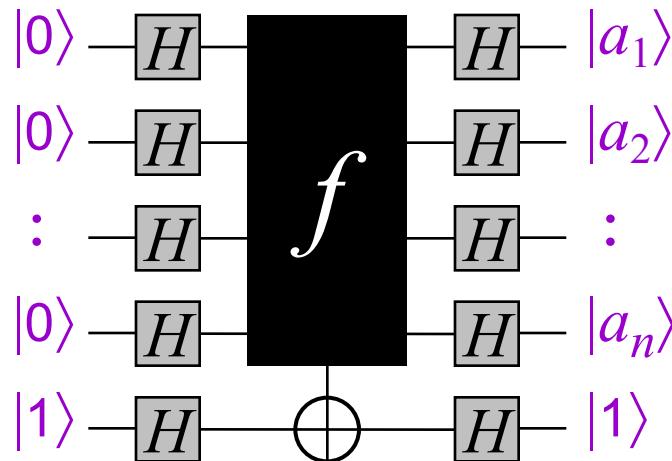

Goal: determine a_1, a_2, \dots, a_n

Classically, n queries are necessary

Aside: Bernstein-Vazirani problem II

Let $f(x_1, x_2, \dots, x_n) = a_1 x_1 + a_2 x_2 + \dots + a_n x_n \bmod 2$

Given:

Goal: determine a_1, a_2, \dots, a_n

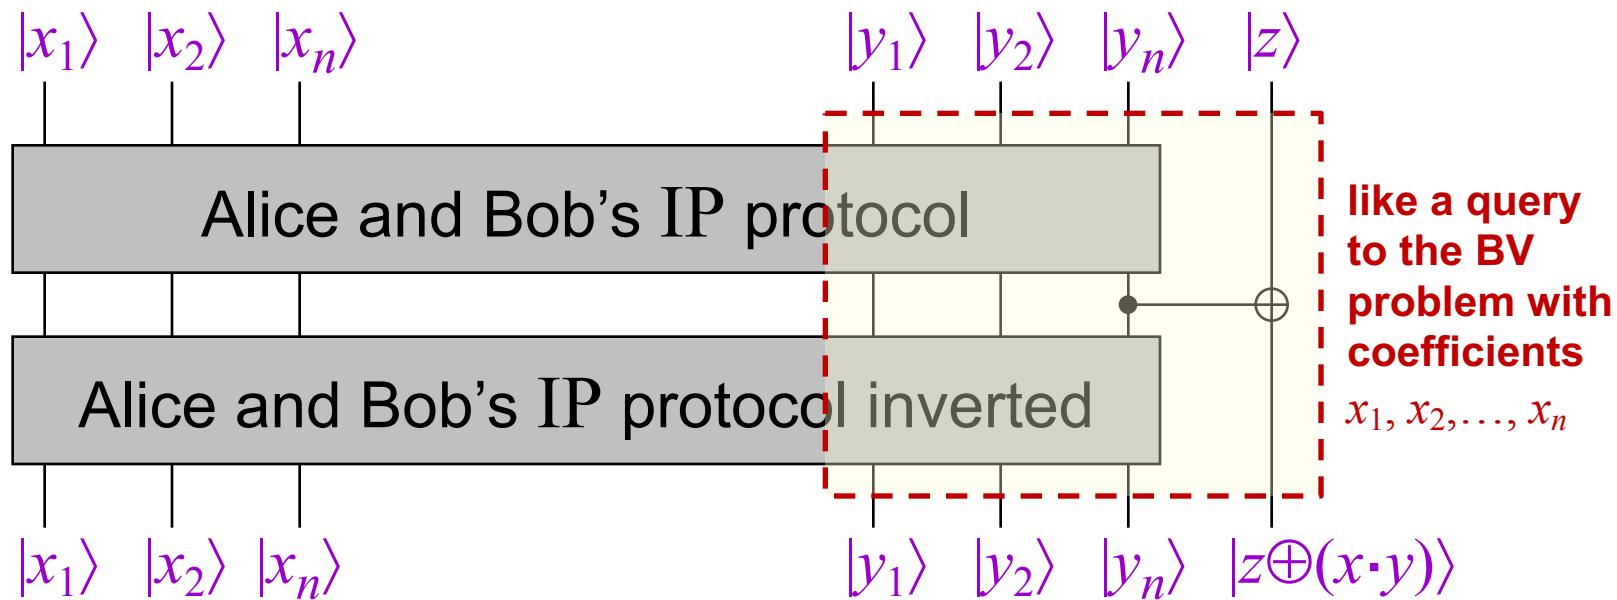

Classically, n queries are necessary

Quantum mechanically, 1 query is sufficient

Lower bound for inner product I

$$x \cdot y = x_1 y_1 + x_2 y_2 + \dots + x_n y_n \bmod 2$$

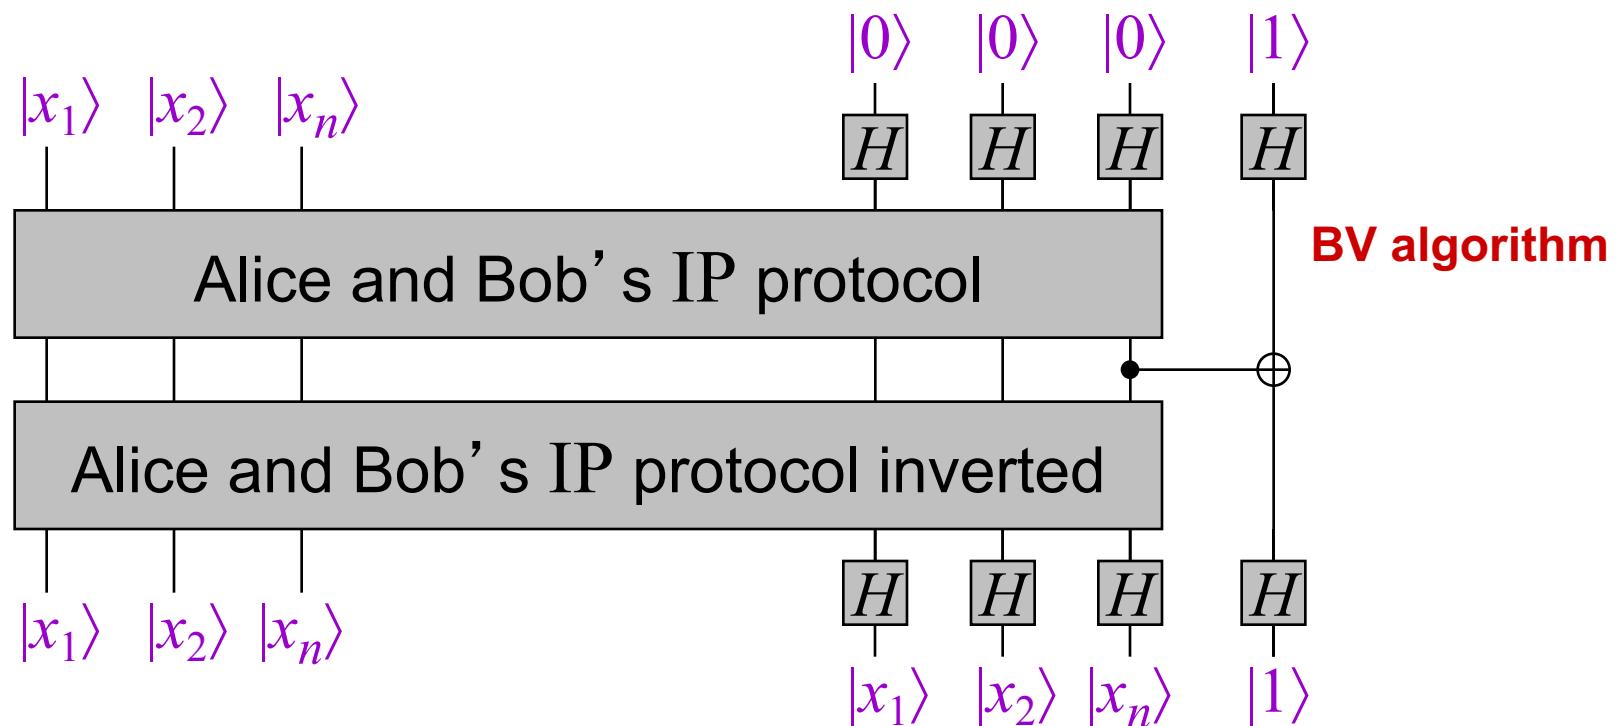

Proof: $|x_1\rangle |x_2\rangle |x_n\rangle$

Lower bound for inner product II

$$x \cdot y = x_1 y_1 + x_2 y_2 + \dots + x_n y_n \bmod 2$$

Proof: $|x_1\rangle |x_2\rangle |x_n\rangle$

Since n bits are conveyed from Alice to Bob, n qubits communication necessary (by Holevo's Theorem)
